

Which model matches the observed family resemblance?

Higher education · English male birth cohort, 1860–1919 · PNAS Table 2

◆ Observed correlation ● Phenotypic assortment ■ Genetic assortment

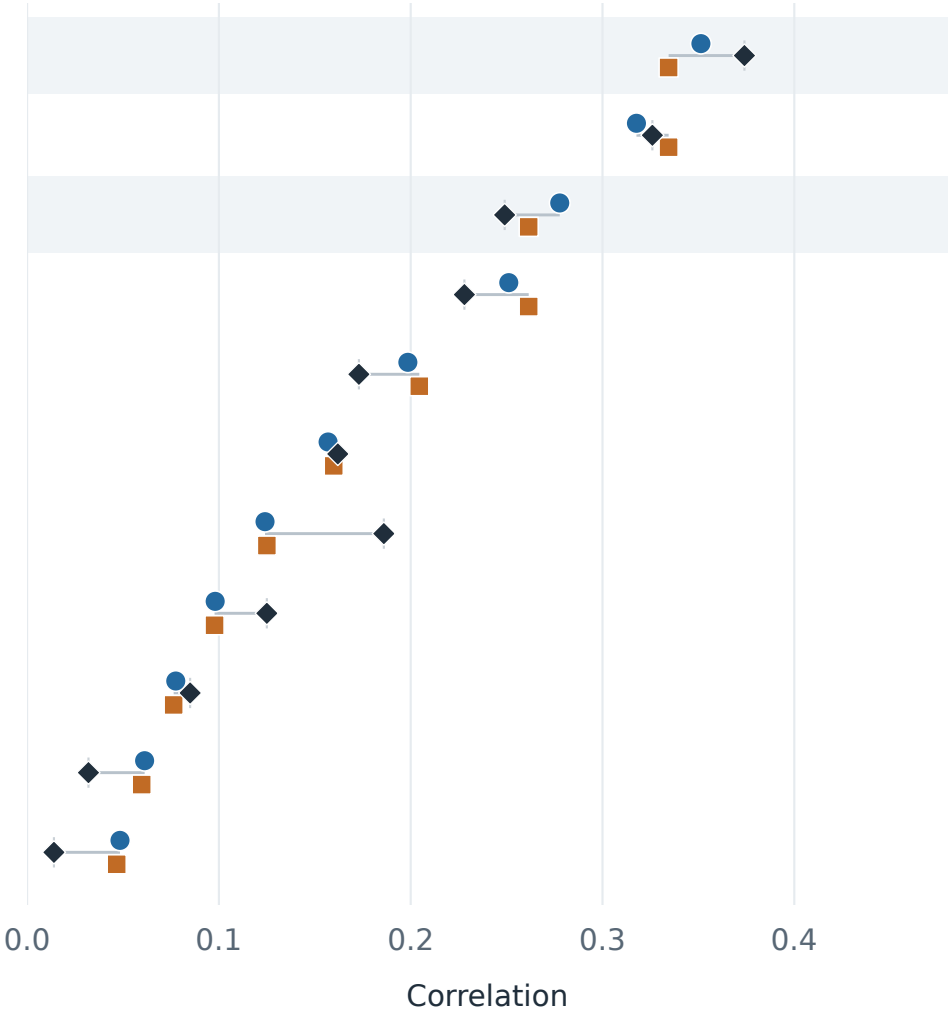

$\theta = 1$ | No measurement error

Squared error: phenotypic 0.0270 · genetic 0.0103

θ free | Measurement error allowed

Squared error: phenotypic 0.0093 · genetic 0.0103

Shaded rows are lineal relatives. Small vertical offsets separate the markers; only horizontal position measures correlation.

Fits minimize unweighted squared errors in correlation levels across all 11 relationships. No observed spouse moment is included.

Genetic predictions are unchanged when θ is freed: only $\theta \times h^2$ is identified. Observed correlations are estimates, not known population truths.
