

Both models assume $\theta = 1$

Book Table 4.5 · Equal-weight least squares in log correlations · Same axes

1. Constraint not imposed: $h^2 = \exp(a)$

2. Constraint imposed: $h^2 = m/r$

Left: three free coefficients. Right: directly fitted in r and m , with $h^2 = m/r$.

Only the equality constraint is imposed; no upper bounds. The right-hand fit implies $r > 1$ for six outcomes.
